

Here are five conceptual questions on Conditional Chains in LangChain:

1. What is a conditional chain in LangChain, and when would you use one instead of a sequential or parallel chain?
2. What is the purpose of RunnableBranch in LangChain, and how does it decide which chain to execute?

In the following code, what is the role of the lambda function?

```
conditional_chain = RunnableBranch(  
    (  
        lambda x: x["sentiment"] == "positive",  
        positive_chain,  
    ),  
    negative_chain,  
)
```

3. If multiple conditions are provided in a RunnableBranch, what happens when more than one condition evaluates to True?
4. Suppose an LLM classifies a movie review as "neutral". Explain the complete execution flow from receiving the review to producing the final response using a conditional chain with three branches (positive, neutral, and negative).
